For today

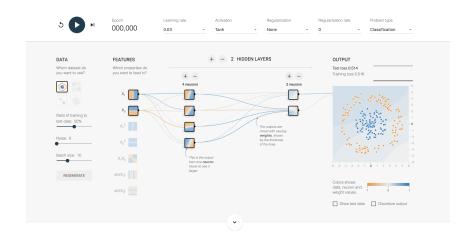

- Variants of autoencoders
- Illustration on MNIST
- Jump starting assn7

Minimal neural network: Recall

- First discussed a logistic regression model
- Then a simple 2-layer network, backprop calcs
- Toy data: 3-class spirals (TF playground and today)
- Your job: Extend starter code

These types of networks are sometimes called *multilayer perceptrons*

Interactive visualizations

Classification

For classification we use softmax to compute probabilities

$$(p_1, p_2, p_3) = \frac{1}{e^{f_1} + e^{f_2} + e^{f_3}} \left(e^{f_1}, e^{f_2}, e^{f_3} \right)$$

The loss function is

$$\mathcal{L} = -\log P(y | x) = \log \left(e^{f_1} + e^{f_2} + e^{f_3}\right) - f_y$$

So, we have

$$\frac{\partial \mathcal{L}}{\partial f_k} = p_k - \mathbb{1}(y = k)$$

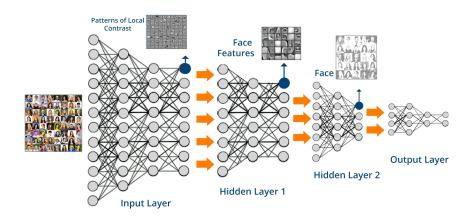

Further reading: http://neuralnetworksanddeeplearning.com/ Disclaimer, I haven't "vetted" this online book.

Examples

Let's go to the spiral data notebook

Deep neural networks

Using goal-driven deep learning models to understand sensory cortex, Yamins and DiCarlo, 2016, ${\tt https://www.nature.com/articles/nn.4244}$

Autoencoders

- Unsupervised learning methods
- Squeeze high dimensional data through a "bottleneck" of lower dimension
- Train to minimize reconstruction error

Autoencoders

 $[\]verb|https://github.com/ardendertat/Applied-Deep-Learning-with-Keras|\\$

Important aspects

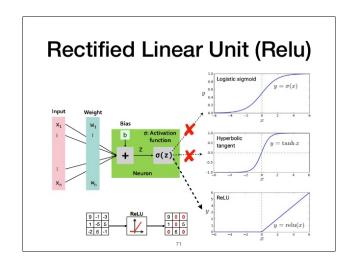

- Unsupervised: No labels used, discovers useful features of input
- Compression: Code reduces dimension of data
- Lossy: Input won't be reconstructed exactly
- Trained: The compression algorithm is learned for specific data

Deep architecture

 $[\]verb|https://github.com/ardendertat/Applied-Deep-Learning-with-Keras|\\$

Activation functions

Simple autoencoder example: Single hidden layer

Encoder network of the form

$$h = \text{ReLU}(Wx + b)$$

decoder network is

$$\widehat{x} = \text{ReLU}(\widetilde{W}h + \widetilde{b})$$

Objective function:

$$\mathcal{L} = \frac{1}{n} \sum_{i=1}^{n} \|x_i - \text{ReLU}(\widetilde{W} \text{ReLU}(Wx_i + b) + \widetilde{b})\|^2.$$

ReLU(x) = max(0, x), applied component-wise.

Simple autoencoder example: Single hidden layer

Encoder network of the form

$$h = \text{ReLU}(Wx + b)$$

where $W \in \mathbb{R}^{H \times D}$ and $b \in \mathbb{R}^H$, decoder network is

$$\widehat{x} = \text{ReLU}(\widetilde{W}h + \widetilde{b})$$

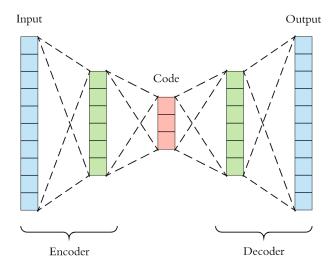

where $\widetilde{\boldsymbol{W}} \in \mathbb{R}^{D \times H}$ and $\widetilde{\boldsymbol{b}} \in \mathbb{R}^{D}$.

Objective function:

$$\mathcal{L} = \frac{1}{n} \sum_{i=1}^{n} \|x_i - \text{ReLU}(\widetilde{W} \text{ReLU}(Wx_i + b) + \widetilde{b})\|^2.$$

ReLU(x) = max(0, x), applied component-wise.

2-layer architecture

2-layer architecture: Code of dimension K

Encoder network of the form

$$h = \text{ReLU}(W_1 x + b_1)$$
$$c = \text{ReLU}(W_2 h + b_2)$$

Decoder network of the form

$$\widehat{h} = \text{ReLU}(\widetilde{W}_1 c + \widetilde{b}_1)$$
 $\widehat{x} = \text{Sigmoid}(\widetilde{W}_2 \widehat{h} + \widetilde{b}_2)$

Objective function: binary cross-entropy

$$\mathcal{L} = -\frac{1}{n} \sum_{i=1}^{n} \sum_{j=1}^{d} (x_{ij} \log \widehat{x}_{ij} + (1 - x_{ij}) \log(1 - \widehat{x}_{ij}))$$

Simple example – code of dimension K

Encoder network of the form

$$h = \text{ReLU}(W_1 x + b_1)$$
$$c = \text{ReLU}(W_2 h + b_2)$$

where $W_1 \in \mathbb{R}^{H \times D}$ and $b_1 \in \mathbb{R}^H$, and $W_2 \in \mathbb{R}^{K \times H}$ and $b_2 \in \mathbb{R}^K$

Decoder network of the form

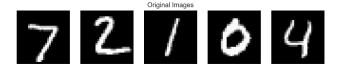

$$\widehat{h} = \text{ReLU}(\widetilde{W}_1 c + \widetilde{b}_1)$$
 $\widehat{x} = \text{Sigmoid}(\widetilde{W}_2 \widehat{h} + \widetilde{b}_2)$

where $\widetilde{W}_1 \in \mathbb{R}^{H \times K}$ and $\widetilde{b}_1 \in \mathbb{R}^H$, and $\widetilde{W}_2 \in \mathbb{R}^{D \times H}$ and $\widetilde{b}_2 \in \mathbb{R}^D$

Objective function: binary cross-entropy

$$\mathcal{L} = -\frac{1}{n} \sum_{i=1}^{n} \sum_{j=1}^{d} (x_{ij} \log \widehat{x}_{ij} + (1 - x_{ij}) \log(1 - \widehat{x}_{ij}))$$

MNIST data

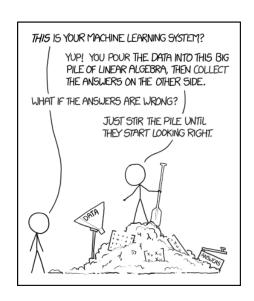

$$28 \times 28 = 784 = D$$

It cuts both ways...

numpy keras

Implementation using Keras

```
input_size = 784
hidden_size = 128
code_size = 32

input_img = Input(shape=(input_size,))
hidden_1 = Dense(hidden_size, activation='relu')(input_img)
code = Dense(code_size, activation='relu')(hidden_1)
hidden_2 = Dense(hidden_size, activation='relu')(code)
output_img = Dense(input_size, activation='sigmoid')(hidden_2)

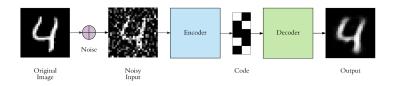

autoencoder = Model(input_img, output_img)
autoencoder.compile(optimizer='adam', loss='binary_crossentropy')
autoencoder.fit(x_train, x_train, epochs=5)
```

Adam optimizer

- Variant of stochastic gradient descent where separate learning rate (step size) is maintained for each network weight (parameter)
- Each step size adapted as learning progresses based on moments of the derivatives

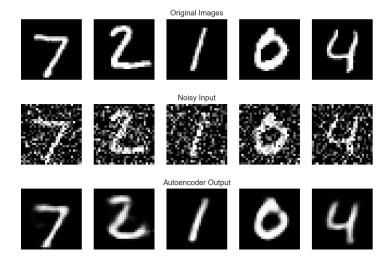

[&]quot;Adam: A method for stochastic optimization," D. Kingma and J. Ba, https://arxiv.org/abs/1412.6980

Variant: Denoising autoencoder

- Feed in noisy data
- Train to match to denoised data

Example result on MNIST

Variant: Sparse autoencoder

- Add penalty to encourage sparsity
- Forces autoencoder to discover interesting structure in data

In Keras this is easy to do:

```
code = Dense(code_size, activation='relu',
activity_regularizer=l1(10e-6))(input_img)
```

Sample code

Let's take a look at the starter code autoencoder-demo.ipynb

Comparison

Let's consider autoencoders in comparison to other methods:

- PCA
- Bayesian inference
- Topic models
- ...Variational autoencoders (IML)

Summary: What did we learn today?

- Autoencoders compress the input and then reconstruct it
- Bottleneck forces extraction of useful features.
- Will overfit and "memorize" the data
- Overfitting mitigated by denoising autoencoders
